Dear Marina,

A few updates

1) I spotted an error in the files I sent you last week. In each file there was a typo in one value of the vibrational cross sections. Find attach corrected files.

2) I wonder whether it is possible to implement rotational excitation in a different manner in your code. Instead of using a cross section set and a typical excitation energy I wonder if we can use results from Cravens and Korosmezey (1986) (attached).

They present a simple formula for the cooling rate R (eVcm3s-1) due to to rotational excitation as a function of T_n and T_e. By multiplying R with N_n and N_e I guess that it gives the amount of energy (eV) transferred from electrons to H2O molecules (through rotational excitations) per second and cm-3. Please think about if this can be used in any way... =)

3) I will come to London on Friday.

4) I have contacted Annie telling her about the T58 results and asked for data for additional flybys. I also asked her if she will attend the EPSC and if we can see each other to discuss details of the nightside project. So far no reply.

Cheers/

Erik
